Figs. E1-A through E1-F Case 16. Anteroposterior (Fig. E1-A) and lateral (Fig. E1-B) elbow radiographs showing suspicious early loosening of the humeral component two years after primary total elbow arthroplasty.
Anteroposterior (Fig. E1-C) and lateral (Fig. E1-D) postoperative elbow radiographs made after index revision of the humeral component. Intraoperative culture yielded an unexpected growth of *Staphylococcus epidermidis*. 
Anteroposterior (Fig. E1-E) and lateral (Fig. E1-F) elbow radiographs made eight years after the index revision, showing repeat loosening of the precoated ulnar component. (The patient had a strut allograft fixation of the ulna to treat a periprosthetic fracture during the eight-year interim period.)
