Figure 3. Immunosuppressant therapy decreased the amount of intraparenchymal CD8+ cells more than CD4+ cells. A-B: immunohistochemical stain for CD8 in presenting biopsy (A) and after immunosuppressant treatment (B) in patient #2. C-D: immunohistochemical stain for CD4 in presenting biopsy (C) and after immunosuppressant treatment (D) in patient #2. There is background staining of sinusoidal endothelial cells for CD4, and only perinuclear dark staining (black arrows) as those seen in portal tracts (internal control) is considered positive (the same intensity as in lymph node control, not shown).
